

field of the Object Shooter component in ShipB. Save the scene and start playing the game.

So, now we have two ships that are firing the bullets, but the bullets do not actually affect the health of the other ship. The UI also shows only the shield and the score of a single ship. As ShipA is located at the $-5X, 0Y$ position, move ShipB to the $5X, 0Y$ position, so the two players start on the left and right side of the screen. This is also reflected in the player controls, on the left and right side of the keyboard. As the camera is no longer tracking the ships, both the spaceships can easily move out of the screen. We will be fixing this in the next step.

On top is the boundary box with the Polygon Collider 2D component, and on the bottom is the spaceships being unable to move out of the playing field.

There are many ways of doing this, which is mostly through the use of scripts. Since this is a basic tutorial, we will be using an approach that works for very basic games. Note that this approach is not at all recommended for finished games, that are to be published. It is better to get more into Unity and use scripts to make sure that the ships do not stray out of an imaginary perimeter. We will be using a physical restraint on the movement, in the form of a box without a fill, but with a stroke. These are walls that are drawn
