

just outside the field of view, and the ships will simply be unable to move beyond those walls. One of the situations where such an approach fails, is on a device with other dimensions than the one you are building the game on. The field of view of the camera is contingent on the screen dimensions and aspect ration of the device on which the game is being played.

Take a screenshot of the scene view, and move over to an image editor. Draw a box around the camera field of view. Remove the print screened image, and save the box as a transparency. We will call it boundary-box. Drag the boundary box into the Scene panel, and scale it so that it is just outside the view of the camera. Now, add the Polygon Collider 2D component

The two spaceships harmlessly blasting lasers at each other.

to this box. Do not add the Rigid Body 2D component, as we do not need the boundary box to react to the ship... we do not need it to fall because of gravity, or move because it bounces off the motion of the ship. Now play the game. The ships cannot leave the play area for some magical reason, which we know is the boundary box out of view.

Next up, we will be fixing the UI. To do this, duplicate the `UIInterface` prefab, twice, and rename them `UI-ShipA` and `UI-ShipB`. Then drag and drop the Prefabs into the Project folder, to a suitable directory. You will be prompted to modify the original prefab or create a variant. Choose to create a variant, which forks out the prefab to another version, whose components and attributes can be modified without affecting the original. Now, add both the UI prefabs into the scene. When working with the UI, we need to move to the Game view, and not use the Scene view, which is where most of the game design process occurs.

Now we have to change the UI. Go to the `ShipB` `GameObject` and add the `Health System Attribute Component`. Also make sure that `ShipB` is
