

gives the most precise control, the speed of projectiles that balances out too much power with too little fun, the exact positions of the asteroids in the playing area... and basically the values of all the attributes of all the components in the project. You can remove all the Destroy For Points At or the Modify Health components from the asteroids to prevent them from getting destroyed by the lasers, or affect the health of the spaceships. If there is something that you intend to add to the game that is not supported natively by Unity Playground, you can add your own custom scripts. Do not be scared of this bit, it is not as complicated as it looks. You do not even need to know a coding language, although we will be using C#. Right click on a folder in the Project panel, and click on **Create > C# Script**. Now, rename the new script. Double click on the script asset, and it will open in a text editor of your choice. We like to use Notepad++, but you can use

The original Asteroids game

notepad just as well. By default though, the script opens in Visual Studio, which requires a sign up and sign and and what not. You can now search for the specific functionality that you want to add on the internet, and chances are that Unity's great community has already come up with multiple scripts that can do exactly what you need. Just copy and paste the script, and add it as a Component to the relevant GameObject.

In fact, there is never really an end to this process of improving the game, you just have to stop at some point and decide that you do not want to invest any more time in this particular game. Have fun designing the level!
