

need the camera to track the ship, and we do not need the boundary box to restrain the ship. Open the scene, and save it as `sh_racer`. Delete all the GameObjects in the scene except the Main Camera, BG_Space and MyShip. The idea is to make a game where the Player has to race around a track. Now, you can drag in a lot of GameObjects into the engine and create a track in the game, but we will be using an image editing track to create one transparent racing map, so that it can be imported as a single sprite into the Engine, and given all the appropriate Components at once. This way, you will not need to handle tens, or maybe even hundreds of different GameObjects in the hierarchy panel. Remember that you need a high resolution transparent graphic, with a starting point and an ending point, and plenty of curves. The approach allows us to very quickly design a very large track. Locate the `Assets > Images > Nature > Stone3` image in explorer, get it into photoshop, and convert the .png into a brush by going to `Edit > Define Brush Preset`. We downloaded some decorations to put around the track, such as planets, stars and spaceships through ya-webdesign.com, but you can choose your own.

The decorations to be peppered around the racetrack.

Then change the brush preset, by giving it enough spacing so that two adjacent rocks do not touch each other, but are still close enough to prevent the spaceship from passing through. Apply a significant size jitter in Shape Dynamics (we used 36%), a slight hue jitter in Colour Dynamics (7%), and check the Smoothing box. Then, pick the foreground and background
