

Also, add the Modify Health Component, so that the spaceship loses health every time it touches the track. You will probably need to reduce the value for the Friction and increase the value for Angular Friction Components on MyShip to give more precise controls for the racing game. Ideally, the spaceship should be so fast that the player is repeatedly forced to take his hands off the booster engines and slow down the ship to navigate corners. The mass and friction should also be tweaked in such a way that every time a collision occurs, the player is more likely to make more mistakes and collide a few more times. Make sure the Health System Component is added to MyShip, and be generous with the health value. Something like 20 should

Placing decorations round the "racetrack"

be good, which means that the player can only touch the edges of the track 20 times over the course of a circuit. A lower value makes the game more difficult, while a higher value makes it easier. The blaster GameObject can also be deleted, as the ability to fire is irrelevant in this game.

Then, we can go on to pepper the decorations around the track. Simply drag and drop them into the Hierarchy panel, at different positions around the track. Unless you are using the same asset many times over, there is no need to convert these GameObjects into Prefabs. We will be adding certain movements to some of the game objects, to make the surroundings more dynamic. To do this, we will be using the Patrol Component on the decorations. Doing so however automatically adds the Rigid Body 2D Component. Since we are using the Patrol component and specifying where the GameObject has to move, there is no need to set the Gravity Attribute value to 0.
