

this is a dangerous world. Now let us find a suitable gap in the floor and fill it with acid. If you have not created such a niche, do so now using the Tile Palette. The acid block will most certainly not fit perfectly into the space for it. You can use the Rect Transform tool to resize it, but that is not the best way to make it fit as it may stretch the acid too much in a particular axis. Instead find the Water Area component, and change X and Y values as per the requirement. This makes sure that you can always fill in any amount of area with acid, and make the liquid look consistent wherever it is used in the game.

Making sure two platforms align.

Next, we will be adding the moving platforms that we planned for. Go to **Prefabs > Interactables** and find one of the two Moving Platform Prefabs. It does not matter which one you use, the difference between the two is purely cosmetic. The platform can move back and forth between two points, let's call them A and B. Just drag the platform into the scene, at point A. One of the things you will notice while doing this is that the moment you drag the platform into the scene, it gets automatically added under the Gameplay header in Hierarchy. Here, Unity 2D Kit is making sure that the various elements that make up a complex game are organised properly. These are just empty GameObjects, appropriately named, with dashes used as spacers. You can create one of your own called “-----decorations-----”, and sort all the sprites that you added to the game under this header.

Click on the Moving Platform GameObject, and you should see something different about it. Instead of one Move gizmo, it actually has two, with a red line between them. These are the two points between which the platform will move in a straight line. You can use the Move tool to position the second Move gizmo. In the game, the platform will now travel between these two
