

The Damager box does not initially align with the Pushable box.

same as Ellen. While Ellen has a Starting Health of 7, Spitter has a Starting Health of 1. We will leave this value as it is, and instead focus on the box. We need to make the box do damage, the same as the acid and the spikes. Now click on the PushableBox Prefab, and go to the Inspector panel. Click on Add Component, and look for Damager. This will add the Component with a green rectangle that does the damage. This green rectangle will not be aligned with the box, so you will have to drag the nodes along the edges and position them outside the edges of the Box Collider 2D gizmo. If the Damager box is within the Collider, then it will not damage the enemy. Now, we need to make sure that the box harms only the enemy, and not Ellen. Most of the setup to achieve this is already done. If you click on the Ellen Prefab you will see that she is sorted into the Player layer right on top of the screen, while Spitter is sorted into the Enemy layer. These layer allocations are functionally the same as the tags that we used earlier, and are different from the Sorting Layer Attribute in the Sprite Renderer Component. Select the PushableBox component again, and go to the Damager component again. The Hittable Layer attribute is set to Nothing by default, which means the box does not do damage to anything. If you change it to Everything, the box will remove 1 health from any Prefab or GameObject with the Damageable component added to it. We need it to only harm the enemy, so we will set it to Enemy. Note that you can select multiple layers that a single Prefab can damage, and do not have to restrict it to just one type of GameObject or Prefab. If you play the game at this point of time, the box will fall down on Spitter, and kill him. **d**
