

On Enter () Attribute, there are two events prepopulated. These are the events for playing the audio clue, as well as generating the particle fx. You can chain up multiple events here that get triggered when you activate a switch. For example, you can open a door, and start moving a platform at the same time. There will be two empty events by default. Click and drag the MovingPlatform (2) Prefab into the field that says None in one of the two empty events. The drop down menu in the event associated with MovingPlatform (2) will go from an inactive No Function drop down box to an active No Function drop down box. The drop down menu will be populated with the Components of the associated Prefab as the top level menu, and the Attributes of each of those Components as the submenu. This means that the switch can be used to modify all kinds of Attributes within the

Activating the Switch while already standing on the platform.

Components of associated Prefabs, and it is possible to do this all at once for many Prefabs at a time. We just want the platform to start moving, so go to the Moving Platform menu, and select the StartMoving () attribute. This ticks the checkbox in the MovingPlatform (2) Prefab, which will then start following the predefined path. The reason that the Attributes have values such as MovingPlatform.StartMoving and WakeUp (), is because all the coding is represented visually within the project and the engine is actually writing the code for you in the background as you are doing all of this clicking, dragging, selecting and modifying. In the background, there are If and Then statements, and what you just did is will cause a line in the code to activate, something like `MovingPlatform.StartMoving = "True"`.
