

lot of tiny and slow moving stars. Make sure the Gizmos are visible, so you can see a faint blue line that indicates the size of the generator. Close the Shape section, and go back to the top level attributes of the Particle System Component. Change the Start Speed to 0.3, which will make slow moving particles. However, you will now notice that the particles disappear before they even reach one fourth the way across the scene. To fix this, extend the Duration Attribute till the particles reach all the way across the scene. We had to use a value of 62. Just a couple of Attributes towards the top, there is a checkbox called Prewarm. Make sure that this is checked. What this does is, when you start a new game, the particle generator will behave as if it has already been generating particles for some time. This means, the stars will not suddenly start appearing from the right of the screen, but instead you will get a steadily moving starfield in the background.

The rectangular particle emitter

Next, reduce the Start Size to something really tiny such as 0.3. Open up the Emission subsection, and reduce the Rate over Time to something close to 5. Next, copy and paste this particle emitter in the Hierarchy Panel, and rename it to `foreground_stars`. The idea is to have another layer of stars, these ones are twice as large as the background stars and also move twice as fast. What this will do is give a nice parallax effect to the background, and the illusion of depth where there really is none. All the settings are not carried over to `foreground_stars` when the GameObject is duplicated. You will need to check the Prewarm box again. Change the Start Size and Start Speed to 0.6. Make sure that in the Renderer section, the Max Particle Size is set to 0.6, which is set to 0.5 by default. The Sorting Layer ID remains set as Background, but change the Order in Layer value to -19. Close the Renderer section and scroll back to the top. The Start Lifetime value can be
