

ship from OnlineLabels. It has six barrels in the front, four tiny ones and two large ones. There are also vents on the back, and bombs on the sides. We will leave the bombs as they are, but utilise all the barrels. We will be firing four streams of bullets, streaming out particle trails from the vents, and firing missiles as well. While the guns will fire fast moving projectiles, the missiles will be slower, thus more difficult to time and aim, but also deal more damage. We will also be adding splash damage to the missiles. Let us go about adding all this to the ship, but first, we will have to start with the basics.

Import the .png of the ship into the Project panel. This was originally a red ship, but we used the hue slider on Pixlr to change it to a green ship. We renamed this new image as player-ship, which is the name of the Game-Object we wanted to use in Unity. Now, when the image is imported, and then dragged into the Hierarchy, the GameObject automatically has the intended name. Use the Ctrl button along with the rotate tool to turn the ship 90 degrees clockwise, so that it faces the right side of the screen. Also scale it so that it is really small. We need to allow for plenty of horizontal and vertical movement within the screen, and also allow the ship enough space to maneuver around a lot of bullets from the enemies. The player-ship can be positioned towards the left side of the screen, this is where it will start. In the Inspector panel, use the Transform component to position the ship exactly along the Y axis, by keying in 0 into the Y axis attribute. We will not be using the Push and Rotate script like we did for the base game though. There are two reasons for this. The first is that this game does not require the ship to be able to rotate, in fact, in such a game it would make aiming difficult, and the controls wonky. The enemies will be coming in from the right, and the ship will always be moving towards the right, even though this is only an illusion. We merely need the ship to move upwards and downwards, as well as forwards and backwards. To do this, we will be using just a single script to control the movement, instead of both rotate and push. Go to **Scripts > Movement** after double clicking to select the player-ship GameObject in the Hierarchy panel, then drag and drop the Move script. You can also click on Add Component and search for and add the Move script.

Now this will require some tweaking, just to get the spaceship moving right. Tweak the Mass and Linear Drag settings until you have something that works for you. Remember to set the Gravity Scale value to 0 or the ship will just fall off the screen. We set the Order in Layer value of the
