

designer. There are many more elegant ways of achieving the same result through scripting. We will be using this correct approach now.

Right click in the Project Window, and click on **Create > C# Script**. Give this new script a name, “bound”. This is the script we will be using to make sure that the spaceship does not exceed the limits of the frame. For this, we will be using `Mathf.Clamp()` function in Unity, which restricts certain values within specified limits. Here, it is restricting the movement of the ship to within what is visible on the screen. Now open up the script in the editor, and you will see the default prepopulated script, which looks like this:

```

• using System.Collections;
• using System.Collections.Generic;
• using UnityEngine;
•
• public class NewBehaviourScript : MonoBehaviour
• {
•     // Start is called before the first frame update
•     void Start()
•     {
•
•     }
•
•     // Update is called once per frame
•     void Update()
•     {
•
•     }
• }

```

Now, our script has a single line of code, and is so simple that we will actually be removing what is considered the bare minimum by Unity. The entirety of our script looks like this:

```

• using System.Collections;
• using System.Collections.Generic;
• using UnityEngine;
•
• public class bound : MonoBehaviour
• {

```
