is the random corruption of files. Arbitrary files can usually be rendered corrupted, or only be occasionally used. Corrupted files may also show an error message that can be used to diagnose the reason for them suddenly becoming unusable, but on multiple occasions, they don't. Corrupted files are caused by a vast host of infectious malware that can spread throughout the computer and render it unusable if not detected early enough. Antivirus software can be used to detect and remove such malware.

2. Conflicting hardware:

When more than one application attempts to use the same piece of hardware concurrently, hardware conflicts occur. This can lead to application crashes as well as computer crashes. Hardware conflicts make it extremely difficult to use one's own machine and are also very difficult to detect when using it. The easiest way to identify a potential hardware conflict and to resolve the same is by using the Windows Device Manager Application. Hardware conflict issues are conveniently highlighted in the Windows Device Manager application and can be solved using the troubleshooting mechanism.

3. Loud fan:

One of the easiest ways to detect a system that is about to crash is through a noisy system fan. More often than not, a loud system fan means that your system is being exposed to a significantly higher amount of load. A noisy fan basically means that your system fan is running at a very high rpm in order to deal with the large amount of heat being generated by your machine. Overheating of the device can be caused due to a number of reasons – most
