

often due to significant usage of the CPU memory. This can also be due to problems with the hardware, such as dust or dirt being accumulated on it, rendering the cooling process inefficient. In case the problem is due to memory over-usage, use the task manager to detect the app that is leading to the problem and troubleshoot. If the same is due to a hardware issue, open the CPU and clean the fan as well as the accompanying hardware with a dryer.

4. Loud hard drive:

Another commonplace and easily diagnosable feature of an unhealthy machine is a noisy hard drive. Hard disk drives can make a significant amount of noise if their mechanical components are not in a state of use. This can be due to the parts not having been in use for a significant amount of time, developing some mechanical issues, or due to the hard disk being corrupted. Hard drives that have been in use for a long amount of time can also develop these issues. Hard drive issues are among the most common reasons why computers crash, and it is essential to detect and repair these issues as soon as possible. Hard disk problems can also lead to loss of data.

5. Sluggish performance:

Another easily detectable feature of computers that are about to crash can be the slow performance of hardware. Stuttering mouse performance, late detection of new hardware, the late response of keyboards, and intermittent switching off of hardware are all signs that your computer is not doing well and might require some repairs. A number of online software are available to detect which hardware component of your computer is causing the problem. Components such as the motherboard, RAM, and hard disk can also cause issues in the usage of the computer and lead to frequent crashes.

6. Software response:

Poor software response to input can also be a reason for the frequent crashing of your computer. The most frequent reason for this is the installation of a software whose requirements are higher than the specifications of your machine. This can cause a significant slowdown in your computer's performance and may cause it to become unresponsive and eventually crash. It is essential for all users to be responsible for their usage of the device and use it only for purposes with required specifications less than or equal to
