

before you open your CPU. Well, it is true that if you don't know about computers at all, it's better not to touch the side panel to open it.

But even if you know about computers and have friends that can help you, BIOS update is one thing that can get you in trouble as there are not many people who know how to update it properly. We are going to give you some advice or precautions which you need to keep in mind while updating your BIOS on your own, without taking any professional help.

1. First, always, make a backup of your already existing firmware. We can't put more emphasis on this precaution. There are many ways in which a firmware update could go wrong, and if it does, you need to have your backup ready.
2. Always connect your computer and WIFI with UPS when you are updating the BIOS. If the electricity goes out in the middle of the update, your system can crash, and you will end up with the blue screen of death.
3. Also, be 200% sure about your BIOS number, and it's date. It's a rookie mistake to misidentify your motherboard's serial number. Don't rely on the web to tell you the exact number of your motherboard. Open up the lid and see it yourself.
4. Lastly, this point is for computer enthusiasts: when you are updating the firmware of your BIOS, all your overclock settings will be gone. You need to redo the overclocking of your GPU and CPU after the new update is installed. So before hitting the restart button, note down your settings or take a photo.

Difference between UEFI and BIOS

BIOS and UEFI are both firmware interfaces that work as an interpreter for your OS and hardware. In addition to this, both of them start first when you switch on your computer to check if all the hardware present on the computer is working correctly.

BIOS (Basic Input Output System)

1. BIOS came first, and we have been using it since the time of MS-DOS. It sure is an old school firmware, but even in 2020, it still holds up. BIOS reads the first sector of your hard drive to initialize the boot-up process for your operating system.
2. Moreover, BIOS uses Master Board Record (MBR), which uses 32-bit entries to save the information in the hard drive. Thus, it is only capable of making physical partitions to only 4 separate entities.
