

Check your internet connection

Sometimes, a faulty internet connection or router errors can make your PC vulnerable to malware, which can affect your PC's performance. The solution – secure your wi-fi router or internet connection. To secure your router, you need to upgrade your router's firmware constantly. Besides, make sure you change the login credentials periodically. Using high-speed internet connection on low-end PCs can also adversely affect your system performance. In such cases, you may have to upgrade your overall PC.

Conclusion

We hope that this helped you note the key reasons responsible for slowing your PC down. It doesn't end there though, do your own research as well. Take help from public forums to seek advice from experts or hire any professional if you think the issue is beyond your reach. Try to avoid experimenting with your system's security and the C-drive (or whichever drive your Windows is installed on) of your PC without expert supervision. Once your PC's health is restored, do weekly follow ups to keep it running as fast as possible!
