

You will be shocked to know that there are more than 500 companies all over the world that are manufacturing speaker systems and are waiting for you to take them to your home. But, you need to know which one can give you the performance you need while still taking care of your budget.

Given below, we have defined some of the main difference speaker systems that you see in 2.0, 2.1, and 5.1 channel speaker systems. This will provide you with a better idea of which speaker system you need to buy.

2 Channel

First, let's clear this one thing, both 2.0 and 2.1 channel speaker systems come in two variants. Either they come in the form of soundbars that you put up on your wall below your TV to enhance your viewing experience. Or, you get these two-speaker systems in the way of tweeters, these are multimedia systems and get connected to your computer, laptop, and mobile. But, the primary purpose of tweeters is to provide you with the sound of the multimedia files that are playing on your laptop.

Now, coming to what makes 2.0 channel different from the rest of the two-speaker system. When you have a 2.0 channel soundbar or tweeters, you get audio which is coming from 2 channels only. One is on your right side, and the other one is on the left. The main difference that you get here is you won't be getting any base from 2.0 channels from any manufacturer. All the base frequency will come from your left and right channel, which will sound underwhelming if you are a bass lover and love songs that have a heavy beat to it.

If you go a bit higher in terms of cost for purchasing 2.0 channel soundbar you can get pretty loudspeakers that do have some level of the base. Meaning you will be satisfied with it if you are a casual movie watcher.

2.1 Channel

With a 2.1 channel system, you get 2 speakers left and right that provides the respective sound frequency. In addition to these two, you also get 1 subwoofer which transmits only the base. If you want to hear what the base of your song all alone would be like, then you just need to plug the subwoofer, and all you will listen, is the base, no vocals or instruments.

Music lovers use this technique to check if their subwoofer is working fine or not. There are not so many differences between 2.0 and 2.1. The central socket of 2.1 channel speaker is usually located in the subwoofer with all the ports and it works as a central hub and transfers both the sound signal and the power to the other two channels.
