

- They are large storage capacities

They are one of the best storage devices and used worldwide. But what should you do if your hard drive is slowly deteriorating in condition and you could possibly lose all your data? And, what are some of the signs of this happening?

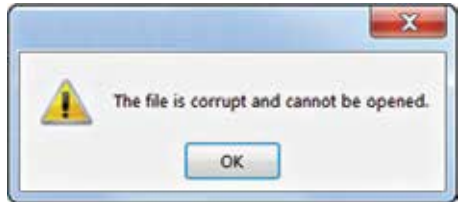

Some of the most important steps are discussed below:

Detecting corrupt files

Corrupted files are one of the first things which can be noticed in the hard disk. The files which do not open in the hard disk and the system slows down

while trying to open it, it's a ringing bell that indicates the hard disk has started deteriorating. Sometimes, those files appear and disappear on their own, periodically.

They are not the files created or saved by someone; they are self-created files. It is a major sign of hard disk failure.

Unusual Sounds

Hearing unusual sounds from the hard disk is another indication that your hard disk is gradually dying. When the disk starts creating noise, it is an indication that it is time to recover all of your data from the drive. This noise is also called a 'click of death' which occurs when the head tries

to write data and recovers from errors while doing it.

The noise also indicates that a part of the hard disk is failing. The part can be any part, either a bearing or spindle motor. So, before the whole drive dies, it's the best time to take the back up from the drive or replace the drive with the new one.
