

reads the data that is recorded by the operating system. However, SMART is sometimes not capable of identifying the hard drive failure, and the warning of the device failure may actually appear before the warning of SMART, so it is not extremely reliable.

All the five methods mentioned above are good options to try and identify whether your hard drive is dying or not.

Now, let's discuss how to identify the deterioration of Solid State Drive.

How do I know when my Solid State Drive is Dying?

Solid State Drive is a different from a hard disk drive. Solid State Drive has relatively lesser issues than hard disk drives do, but that doesn't mean that it cannot be damaged. Solid State Drive runs on a capacitor and power supplies which may malfunction due to power issues or power failure. Solid State Drive has a reputation of corrupting the existing data in case of a power failure, even if the drive has not failed.

As SSD runs on flash memory, it has limited read and writes cycles. In this article, let's get to know about some of the symptoms of an SSD failing so that you can keep a look out for those.

Bad Block Errors

Bad blocks in Solid State Drive are similar to bad sectors in hard disk drives. In this scenario, the computer tries to read or save a file, but takes a longer period of time and ends in failure. In this whole process, the system ends up giving an error message.

Some of the common symptoms of bad blocks are:

- Files cannot be read or written to the hard drive.
- The computer system requires repairing.
- The occurrence of frequent errors while moving files.
