

- Applications that are active often freeze up and crash.
- Applications run slow.

If the computer responds with similar symptoms, the best method would be to run the Crystal Disk Mark or a Smart Reporter Lite to check whether there is any physical problem with the drive. If the problem occurs, it's time to back up the data and buy a new SSD.

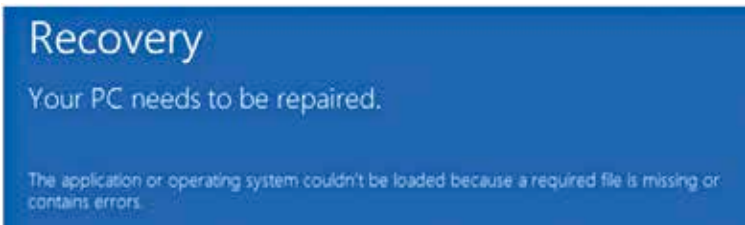

Read/Write Files Stop

The files present in the drive can be affected by bad blocks in two ways:

- The system refuses to write data as it identifies the bad blocks while writing data to the drive.
- The system refuses to read the data as it identifies the bad blocks after the data has been written.

Both the above situations have their consequences. In the first scenario, as the data has never been written, it is safe and not corrupted. The system can resolve it automatically. If the system doesn't, it can be fixed manually by saving the file in a different location or by copying it to the cloud. Once the file has been copied to the cloud, restart the system, and re-copy the files to the drive.

In the second scenario, the data cannot be retrieved easily. There is very little hope to get back the data.

Repair the File System

When the above error message pops up on the screen of the system, usually it happens because the computer has not been shut down properly. There is also a second possibility, i.e., it can be a sign of the development of bad blocks in SSD.

This problem has an inbuilt solution in the system. The computer system has its own to build repair tools for a corrupt file system. Mostly in this scenario, every operating system prompts to run the respective tool, so
