

the steps can be followed to repair the file system. However, do note that there is a possibility of losing some data in this process, and the recovery of that data is difficult.

System Crash While Boot

When the system is crashing at the time of boot but still works fine when the reset button is clicked a couple of times, the issue is with the drive. This can be due to the bad block of a dying drive, so it's better to back up the data before losing it forever.

To cross-check and test and see whether the issue is with the drive, download and run diagnostic tools. Once the data is backed up, try to format the drive or reinstall the operating system.

Read-only Drive

Sometimes, Solid State Drive might refuse to respond and perform any operations that require it to write data to disk. It is not common, but still one of the major issues faced while using Solid State Drive. In this mode, the Solid State Drive still works well in read-only mode. In this case, all the drives are dead, but the data in the drive can be recovered easily.
