

Before throwing the Solid State Drive into the bin thinking it will die, try to reconnect it to an external hard disk or another computer. Do not boot the operating system from the Solid State Drive and use the computer's main drive for it. In this, if the Solid State Drive is functioning in the same read-only mode, it's time to retrieve all the data from it.

Conclusion

If a Solid State Drive or a Hard Disk Drive is about to die, or it's age has almost been close to five years, then the safest option would be to start searching for a replacement and getting a new storage device.

Certain methods can be used to extend the lifespan of the drive are:

- Keep the drive in a cool place and avoid it from extreme temperatures.
- Avoid power off or electric fluctuations.
- There should always be some extra space left in the drive.
