

your eyes. (Unless you want to scare people off!) Another hack of doing this without spending any money is to use your windows cleverly. Ensure that the natural light is falling directly on your face and not behind your body as that will darken your image.

Mounting Your Camera

In addition to the lights, you will have to make sure to place your camera such that the angle is proper, and you don't have to change or modify it mid-way in a video call. A simple way to mount your DSLR correctly is to use a tripod. That will make your camera stable and will give you a steady image.

But, if you're planning to place your DSLR above your screen like a traditional webcam, then it might be a little complicated task. You can use clamps and mounts to fix the camera on the desk and place it on eye level. Another solution is to use a GorillaPod by placing it at the screening arm, but it's not the most sophisticated solution.

Power Supply For The Camera

Now you're almost set for your high-quality video conference. Almost? Yes! Just a few more essential steps that you need to take care of, and then you're all set.

Since you will be using your DSLR as a webcam, there will be constant video transfer and streaming. Your camera has to be kept on, and this heavy load can take a toll on the batteries.

Therefore, you should buy an A/C adapter that can power your DSLR, rather than depending on batteries. While some cameras need specific A/C adapters from the manufacturers, others can be charged through USB-C chargers and battery banks. Therefore, it is advisable to consult your camera's manual to understand your requirements. It is also prudent that you switch off any automatic shutdown option as you don't want that to happen in between a meeting.

Lens

Always opt for the fastest lens available. This means that you need to choose a lens with the least aperture (it is denoted by the number after the f/). The lower the aperture, the more focus will be on you as it will blur your background and make it aesthetically pleasing.

It is recommended to go for f/2.8, at least. The lower you go, the better will be the image.
