

a variety of jobs. In this particular chapter, we will primarily focus on back-end development.

What is back-end development?

There are generally two parts of any web application: the front-end or client-side and the back-end or server-side. The front-end part of the application includes the pages you see and interact with within your browser. The front-end developers develop those pages. But, how exactly are those web pages displayed on the browsers used by the user? What happens when a user inputs something into those pages?

When a user enters a URL, opens a webpage, interacts with animations, clicks a link or submits a form, their browser connects to a web server, which is just another computer that runs a software that helps in delivering

Back-end development involves connecting the user-facing browser with the underlying web server and database

resources like web pages and images. When a web server receives a request for a resource, it needs to respond with that particular resource. Programming web servers to respond with the correct resources is the major domain of back-end developers.

Before a web page or other resources are delivered to a browser, a web application written by back-end developers fills that page with the data that is pulled from a database, which in turn is a separate program that stores and retrieves data. Back-end developers must be acquainted with the programming language that is used to build the web application and the database where the data is stored. Overall, a front-end developer
