

to be accessed not by web browsers, but by mobile phone apps and other programs.

It acts as a smooth and easy to access interface between the user and the complex algorithms and data that lies on the server. It can also be seen as a set of routine protocols that act as a messenger, which takes requests and tells a system what you want to do, and then it returns the response to you.

An API can interact with the back-end developer to provide essential information to the user via different modes like apps, IoT, etc.

The path to becoming a good back-end developer

The journey of a back-end developer is quite complex. He/ she has to face a lot of decision-making moments. There is a variety of tools, frameworks, and software that are available for back-end development, and different companies prefer almost all of them equally according to their requirements.

Let us dive deeper into the basic types of frameworks or tools that are essential for any back-end developer. Many steps occur while responding to a request from a browser, each requiring a different type of software. The combination of technologies used by a particular web server is known as its “tech stack”. A tech stack has different layers or different kinds of important tools.

For each layer of the tech stack, you’ll find there are many choices between software and frameworks. There’s no way to learn them all before you get your first development job, but you’ll find that different web server frameworks and databases work in almost the same way. If you learn a popular language or framework from each layer, you’ll find that there are plenty of companies ready to hire and train you in their particular tech stack. Let’s look at each layer of a typical tech stack:
