

1. Web server softwares:

When a browser connects to the server, the web server software accepts the request. It acts as a mediator that enables the exchange of important information between the browser and the server. Examples of popular web server softwares include Apache, NGINX, and Microsoft IIS (Internet Information Services). IIS is mostly suited for web applications developed particularly for Microsoft's operating system, Windows. Whereas Apache is very solid for heavy functionality and NGINX is also powerful, but is primarily built for high traffic sites. NGINX needs dedicated software to process PHP commands while Apache uses its own tools.

2. Web framework:

The web service software then passes the request off to a web framework. Web frameworks are libraries for programming languages that help back-end developers handle web requests. These libraries save developers from writing basic and repetitive codes from scratch.

There are different programming languages out there, each with multiple frameworks to choose from. They all work similarly, so after you have learned one language and framework, you will find it easier to learn the others. We are listing out the most popular languages and their corresponding frameworks here:

- a. **JavaScript:** It is a language which was originally developed to run inside web browsers to make web pages more interactive. More recently, server software has been released that allows developers to write JavaScript code for back-end as well. Popular JavaScript web frameworks include Node.JS and Express.
- b. **Java:** This language should not be confused with JavaScript. Java language was designed from the ground up to be run on the server-side. Java is as easy to pick up as JavaScript, but the resulting programs are fast enough to handle requests from thousands of users at once. On top of it, Java runs on Bytecode, which helps in cross-platform functionality. Popular Java web frameworks include Spring and JavaServer faces.
- c. **Python:** It is a highly flexible programming language that is easy to learn and use. Apart from back-end development, Python is also very popular for data analysis, web scraping, etc. Popular Python web frameworks include Django and Flask.
- d. **C#:** Microsoft originally developed it as an alternative to Java. If you are going to be working in the Microsoft ecosystem, you will have to
