

for use by a program other than the browser. The most common formats for API responses are JavaScript Object Notation (JSON) and Extensible Markup Language (XML). A back-end developer needs to be able to convert the data to JSON or XML for the server to respond.

Once the code has been written to carry out all these steps for a request, the back-end developer's work is done. The web framework will automatically deliver the completed response to the web server, and the web server will respond to the users' browser. If the back-end developer has written the code carefully and cleanly by avoiding slower, inefficient operations, then this whole request and response process usually takes less than a second. Successful back-end developers rely on other tools besides their programming language and the web framework.

Additional tools

1. Cloud hosting:

You'll need computers to run your finished web app. Gone are the days when most companies ran giant servers and computers in their buildings. Nowadays, most apps are hosted on cloud hosting platforms, which can deploy copies of your app to as many or as few servers as you need. Popular cloud hosting platforms include Amazon Web Services, Heroku, and Google Cloud Platform. Heroku is a cheaper version used by most beginners with a decent pricing range. Amazon Web Services is expensive, but provides excellent uptime and speed.
