

2. Database software:

You'll need to be familiar with the database software itself so you can create the tables and columns that will hold user data. Fortunately, most databases work similarly, and the ORM library handles most of the work of managing the database. Popular database softwares are MySQL, SQL Server, and PostgreSQL.

3. Version control system:

You'll need to have one version of your code running on your web server and another version on your computer while you work on new features. The version control software can help you manage the different versions of your code. It keeps a record of all the changes that you make in your code so that you can track and extract any version of your code or even specific snippets in case of any errors or restorations. Popular version control softwares include Git and Subversion. Git is a popular version control system that is distributed in nature. On the other hand, Subversion is centralized.

4. Documentation:

Interacting with other teams on a project can be a difficult and tiresome process sometimes. Communicating with others should be as easy and efficient as possible. Most of the developers prefer dynamic platforms where they can embed code and images, collaborate live, and have cloud support. Some of the popular platforms for this are Notion, Github, etc.

How to start?

All data managed by back-end developers needs to be presented in HTML web pages. So, even if you are certain, that your goal is to be a back-end developer, it's a good idea to learn the basics of a front-end development first. Front-end developers need to know HTML to give pages structure and cascading style sheets to let you add colours and other styling elements to the pages, and JavaScript programming to make pages interactive.

You can start learning whatever programming language interests you. You might choose a language because it's preferred by companies you want to work for. Java is heavily used at Google and Amazon. You might also pick a language because it has a tool or framework that you like. Python has a lot of great data analysis libraries, so if you are interested in web development and data analysis, Python is a great choice. There are lots of similarities between different programming languages. Once you have learned one
