

2. JPA to create and access a database

Java Persistence API (JPA) is a Java class that provides object-relational mapping and represents the structure of a database table. Hibernate is a famous JPA implementation used in large-scale applications. By default, Spring Boot has a hibernate tool; and it also has a CrudRepository interface for CRUD operations.

3. Using Spring Boot for RESTful web service

Web services are applications that use the HTTP protocol to communicate over the internet. Representational State Transfer (REST) is an architecture for creating web services, and it has elements such as unique identifiers, resource representation, self-descriptive message, and HATEOAS.

You can use Spring Data Rest to create RESTful web services. It is a part of the Spring Data project and offers an easy, fast way of implementation. For testing your RESTful web services, multiple tools are available such as Postman and cURL.

4. User interface using React component library

React is a JS library for user interfaces. The components in React are reusable, independent, and defined by using ES6 (ECMAScripting 2015), a standardised JavaScript scripting language. React ensures faster rendering of the interface with the help of virtual DOM, and you can use JSX to create a styling interface.
