

and Karma. Jasmine is used for testing JavaScript code, and Karma is an automatic test runner that executes the test script written in Jasmine.

5. Creating a RESTful API with Node.js and Express.js

Whenever a request reaches the backend, the server creates a new thread for the request and it releases the thread after responding. To handle millions of requests, this approach is not appropriate. Here comes the importance of Node.js. In Node.js, instead of creating new threads for each request, it uses the same main thread to handle the request.

However, while using Node.js, the programmer has to write a lot of code even for simple user requests. To avoid this case, you can use Express.js, an open-source framework designed on top of Node.js. Express.js is very flexible, and programmers can develop robust APIs.

6. MongoDB

MongoDB is a NoSQL database that stores the information in a JSON-based document. To integrate MongoDB database with Node.js application, you can use one of the most popular NPM modules, and it is called Mongoose. It provides an easy way for data modelling and has built-in features such as validating and querying.

Full-stack development with JHipster

JHipster makes it easier for developers to develop full-stack web applications in less time. Here, developers don't need to spend time integrating technologies and can focus on their actual solution.

1. Client-side technologies

Let's look into the various client-side technologies in JHipster. They are as follows:
