6. Environment setup

Nowadays, it is a necessity to install Node and npm (Node Package Manager) for front-end development. These are tools that provide the proficiency to build and execute Vue applications. Besides, npm is also necessary to install many client-side applications.

For Vue, technically, there is no need to do any installation. It is a JavaScript file that is placed on your webpage. Since multiple files and several libraries are involved in a real-world application, it is not wise to reference those pages manually. Here, we can overcome this problem by using a technology called WebPack. It helps to bundle the client-side script file and also does the transpilation of files. To debug Vue applications, Google Chrome provides a useful plugin called Vue.js Chrome dev tool extension. It is easy to add this plugin to chrome.

For the installation of backend tools, you need to install only two tools; ASP.NET core and PostgreSQL.

For IDE, you can install Visual Studio. Another tool available is the VS Code, a cross-platform light-weight editor. There are many VS code extensions available and Vetur is one of the popular. It has features such as syntax highlighting, IntelliSense, error checking, and code snippets. Some other extensions are NuGet Packet Manager, C# extension, and Prettier. However, VS Code is not an IDE, it is a text editor that provides functionality similar to IDE. It is better to install Visual Studio if you are using Windows.
