

Deploying your web applications

Many technologies are available to deploy web applications. Here we will look into three different scenarios:

1. Deploying on local server using NGINX and Docker

NGINX acts as a web server in the deployment. Using the NGINX configuration file, you can mention the server configuration details.

Docker is a container management tool used to create, share, and deploy containers. With the help of the Docker file, you can create a Docker image for the web application along with the configuration file to start the NGINX web server. Upon creating the docker image, you can run your web application on the local server.

2. Deploying on Heroku

Heroku provides a cloud-based deployment service for your web application. To start with Heroku, you have to create an account (free), then install Heroku CLI – a command-line tool to deploy an application, and finally deploy your application.

3. Deploying on AWS S3 Bucket

AWS is one of the best and biggest cloud service providers. You can deploy your application without installing your server or EC2 virtual machine instance. Here, you can create a bucket and add files to your bucket by providing the right set of permission.

Tutorials and courses

- **Spring boot developer training**

This course provides hands-on experience with Spring Boot and its features that include auto-configuration, Spring data, Actuator, Spring Boot testing, and more. Upon completion of the course, you will be able to develop enterprise-ready applications.

Link: <https://dgit.in/springboot>

- **Learn React.js**

With this course, you will develop a good understanding of React.js, and its essential concepts such as JSX, props, state, and a lot more.
