

AI is also contributing actively to the detection of diseases, helping in making medicines stronger and in predicting stock market trends. All you have to do is type in a few algorithms in your favourite programming language, and you are out there with a whole new software solving problems.

If you want to know more than just basics about this industry, then we have created this roadmap for you.

Learning curve

You might be all geared up to take the journey to the world of AI and build your first AI model, but you cannot just leave out the preparation. Building AI models is nothing less than an adventure, but to enjoy the adventure, you will need proper tools and background. Therefore, to start winning gold, you must begin running the winding tracks of learning.

This is one of the very first steps that require your attention, patience, and determination. Once you are through with this phase, there is no turning back. Hop on, tighten your seat belts, and let the journey begin.

Know your statistics

AI is used in a vast number of applications these days. Your high-school statistics, mathematics, and a lot of your “irrelevant” education from back then, will play a significant role. Probability, classification, clustering, variance, trigonometry up to a certain extent (if you want the machine to move) are a must. You cannot leave out anything from your basic Mathematics and Statistics course, because if you do, you might be in for trouble. Therefore, it is better if you could brush up some concepts before getting your hands dirty.

Start loving languages

No, not your mother tongue, programming languages. The system requires instructions, and you need to convert the instructions the way you want your system to understand them. You have a long list of programming languages that you can use to build your first AI. We will discuss some of the popular ones below:

Python

As with most applications, Python leads the pack with AI too. You get unparalleled support, fantastic community, and so many APIs and support libraries to help you achieve the heights. You name the job and Python has a library ready to save you the number of lines of code required to build
