

Developer++

Becoming a developer was often seen as quite the achievement. Talking the language of the machines was akin to being capable of magic. Then of course, we ended up churning more engineers and developers than most of the other countries in the world. However, with volume comes the dilution of quality. We're talking about the quality of education here. Having overpopulated classrooms and teaching students the basics of technology and everything that comes after isn't an easy task and the end result is that a lot of engineers are simply not employable when they graduate. This is very much different from institutions that focus on practical experience which invariably results in better coders. And the few that do make the cut, know how to code but that's still a far cry from what the industry expects of coders.

So over the years, being a coder has become a simple task but being a better coder is what companies expect. A lot of it boils down to practising your programming skills with patience and consistency. Experimenting and learning newer paradigms is even better. The question then arises as to what you need to be practising, what new programming paradigms and programming languages do you need to learn? Well, that depends on what you want to do. The developer ecosystem has grown to be so massive that there are specialisations and super specialisations within different domains. A coder with HTML knowledge isn't going to be good at building AI models but a person who already knows python and GPGPU computing is much better placed to pivot and take up AI modeling.

This FastTrack is broken down into 9 of the most popular developer sciences that exist in the industry right now and we've focused on what all you should learn, what the industry expects from you and where
