

- SourceTree – Manage GIT repositories with ease
- Vysor – Another great Android emulator
- Drawable Optimizer – Reduce APK size by optimizing image assets with this plugin
- Scalpel – The best tool for beginners to visualize layers. You need this if you think your code gets messy too often.
- KeyPromoter – Use this app to speed up the process with which you get used to keyboard shortcuts
- Butterknife injections – Generates boilerplate code injections with Butterknife library.
- Awesome Android Libraries – Android libraries organized by function, name and license.
- Android Arsenal Libraries – A collection of free Android libraries

Improving debugging and testing

The prickly pain point for every developer, be it Android or iOS is to have a set regimen for the debugging process. But this is exactly the deciding factor that will make you stand apart from beginners and the amateurs. Get your game face on and start running multiple tests, or your code will always remain a legacy. One way to do this is to invest in some quality automated testing tools.

For iOS, XCTest is itself quite good at handling debugging. But if you want to speed up the process, you can go with Appium, Calabash, KIF or Bugfender, all of which are free. Apart from these, check out Application Performance Monitoring tools like NewRelic, Dynatrace, Raygun and AppDynamics. APM tools let you analyze how robust your back-end code is, and also give you a clear picture of user satisfaction.

With Android though, as the number of potential devices is higher, the testing capabilities need to be excited. So we have compiled a list of plugins as well as automation tools you can try out:

- Instabug – The preferred choice of PayPal, Lyft, Buzzfeed and Mashable, this nifty tool lets you beta test and capture detailed error logs.
- LeakCanary – Detect memory leaks and improve stability
- NimbleDroid – NimbleDroid is one that is designed for use at the phinal phase, right before deployment
- Stetho – Android debugging tool by Facebook
- Takt – Check FPS while debugging
- PMD – Cleans up your source code
- Lint – Recommended by Google to ensure no structural problems
