

A good design

What do we consider as good design? What should be present to make the design accessible for the user? Should I add more or less? All these are common questions that should be in your mind. The following are some of the points you need to consider to create an excellent design:

1. **Interactive design** – A UI designer anticipates user behaviour and designs the interface that will meet the user's requirements. Interactive designs drive more users.
2. **Visual design and aesthetics** – Apart from the information and the interaction that guides the user, it is the pleasing aesthetics of the interface that also keeps them occupied.
3. **Information architecture** – The information that needs to be given to the user should be structured and focused on keeping them engaged and at the same time, should not be overstuffed with information.

Although, the actual design that keeps the user engaged varies based on the niche, the optimisation has to be done based on the requirements. For instance, an electronic website like Texas Instruments needs more information and fewer visuals, whereas a website for a photography studio needs more pleasing visuals to make the users aware of their services and quality of work. Same is the case for any UI design. The designer decides what will be chosen to keep the user busy and informed.

UI principles

It is not just a design with information that makes a good UI designer, but also nuances that make you a pro. The following are some of the UI design principles you need to familiarise with:

1. **Colour** – Colours play a vital role in expressing the emotions and keeping someone attracted to your website for a long time. Primary, secondary, and neutral colours determine various aspects and depict emotions such as passionate, calm, sensitive, and informational. Being informed about colours and how each colour is perceived will help create an excellent UI design.
2. **Grid systems** – As mentioned earlier, you need to work on optimising your design. Test various grid systems and test your layout that projects the purpose of the system. Your design and the grid will vary based on the screen size, like in a mobile, watch, iPad, or a phone. Knowing how the spacing between the grids and each cell's placement affects the design is another principle of UI design. 90 percent of users use smartphones
