

- Nagios - Nagios is used for software monitoring for servers and applications. For tips and tricks to get maximum performance, refer <https://dgit.in/nagios>.
- Raygun - Raygun is also a software monitoring application based on cloud and is used for crash reporting and tracking. Know more about raygun and why you should use it in your development processes at <https://dgit.in/raygun>.

All the above-mentioned tools are used extensively by industries and also chosen based on the kind of requirements of the projects. Knowing these tools is very much required for becoming a successful DevOps Engineer and also for making the development process easier for you. Let us now look at the individual roles of these tools.

Source Code Management System - A source control system, which is an also called version control system, is a tool that is used to collaborate and code with each other and also make it possible to track changes. Some of the examples of source code management systems are Git and Github, and Atlassian BitBucket.

Server Automation - The server automation system is a method of bundling the process automation and task automation into a single process. It helps in the efficient deployment of applications and also makes it possible to perform management of physical and virtual systems. The most used examples of server automation tools are Jenkins and Bamboo.

Configuration Management - Configuration management is a process of managing the configuration platform. It is used when we take automation into applications and automate, manage monitor, and design configuration processes. Examples of configuration management systems are Puppet, Chef, and Ansible.

Software Containerization - Software containerization is the process of bundling the application along with the libraries, configuration files, and the frameworks. It is used to make it possible for the application to run in different computing environments and also work more efficiently. The examples of software containerization tools are Docker and LXD.

Container Orchestration - Container orchestration is the process of making the management, scheduling, deployment, and provisioning of containers automatic. One of the examples of container orchestration tools is Kubernetes.

Cloud Platform - Cloud platforms are the platforms that are used to write and run the code for applications on the cloud. It also makes the required
