

- Current web security guidelines
- Have an understanding of the latest coding standards
- Test common vulnerability applications such as Gruyere, WebGoat, Mutillidae, etc.
- Try your skills for breaking applications and discovering potential vulnerabilities in common software.
- Have a prolific understanding of fixing systems with code, designs, usability, functionality, etc.

Know both sides of the application front end (Black Box) and back end (White Box)

• Black Box approach

This testing approach evaluates the functionality of an application without getting inside its implementation structure. So, engineers work with what they have that consists of front end code with HTML structure,

JavaScript, requests, responses, cookies, session identifiers, and other DOM elements. Here, engineers can find vulnerabilities to customise the communication between the server and the client. Most global organisations offer a bounty of programs for programmers and engineers to find vulnerabilities in their services or products in real-time applications such as Microsoft, Google, etc.

BLACK BOX TESTING APPROACH

Black Box Approach for testing

• White Box approach

This testing approach follows the internal structure inside the application to review and evaluate code for finding vulnerabilities. You can test the

approach on multiple open libraries, plugins, or applications built in different programming languages. You can use the apps through different

Approach for White Box technique
