

3. Grey-box Testing

It is somewhat a mix of both white and black box testing. In this method, a tester is partially aware of the internal code implementations, design, or internal working of a software. It is done to find defects that may come due to code syntax error or improper functioning of the software. In this type of testing, a tester can write better test cases as he/she has access to the code, design documents, and database. Hence, it enables the tester to test both sides of the software i.e. user interface as well as internal code.

Advantages:

- Provides combined benefits of both white and black box testing.
- Improves the software as it takes input from both developers as well as a tester.
- It is performed from a user's perspective rather than a developer's perspective.
- Tests both sides of the software i.e. the presentation layer and code layer

Disadvantages:

- It no doubt increases the test coverage but still does not provide full coverage.

What are the levels of software testing?

Testing is broadly divided into two levels. Then, based on the methods described above, they are further broken into several different types.

1. Functional Testing

Functional testing is a black box testing wherein a tester tests the functional specifications of the software. The tester evaluates the output of the system against the input provided and investigates if it meets the specifications to ensure the quality, performance, and correctness of the software. It has the following types:
