

the system with the aim of developing end-to-end results. A tester can test the software like a user, where he or she does not know anything about how the system is architected or coded and expect the response accordingly. This way, it becomes possible for the tester to know how exactly the software is performing and whether it delivers its promises. Black box testing also evaluates all relevant systems such as integrated systems, dependencies, database, UI/UX, web browser or application, and so on.

Top ten Black Box testing tools

1. **Selenium:** It facilitates black box testing with the help of stimulating the user's workflow in the browser. Thus, the tester can evaluate whether a certain story represented by the particular workflow is working effectively.
2. **Appium:** It is similar to Selenium except that it can be accessed on the mobile device browser. As it allows testing on a mobile device, Appium can be used accurately to perform actions on the actual devices.
3. **Applitools Eyes:** The most purified way of black-box testing is said to be Visual UI as it solely operates on the basis of what a user sees. Applitools makes visual testing possible and helps the tester focus on visual differences that are most relevant for current tests, content changes, or layout changes.
4. **QuickTest Professional (QTP):** Just like Appium and Selenium, QTP allows the tester to define a workflow representing a certain user story and evaluate if it is performing as expected.
5. **Coded UI:** It is an excellent choice for the testers using Windows platform for desktop or mobile devices as Coded UI provides simulation for the workflow executed by the users on those particular platforms.
6. **LoadRunner:** Non-functional software tests are generally carried out using Loadrunner.
7. **Veracode:** It provides a comprehensive black-box testing tool along with static analysis, software composition analysis. Veracode is a cloud-based security solution that also provides vendor application security testing and web application perimeter monitoring.
8. **JMeter:** Just like LoadRunner, JMeter is also used for carrying out non-functional tests.
9. **Ranorex:** It allows the user create tests for various steps such as login, storage of data in the user library, and re-using it. Ranorex allows the tester to combine the repository objects and code modules into sophisticated tests.
10. **Zaptest:** It allows the tester to frame scripts against any UI document with one click, execute, and host the test in a private in-house cloud. Zaptest allows
