

Software testing is an activity to examine whether the actual result is the same as the expected result. If both the expected and actual result matches, the system is defect-free. The main intention of conducting these tests is to find bugs and verify that the software is ready to be used. There can be infinite test cases for simple components even. Hence, it is essential to strategically decide on the tests that are feasible based on the time and resources available. Software testing allows users to know about the quality of the software and the risk of its failure.

What is a software test suite?

A software test suite is a container having a set of tests assisting testers in analyzing and reporting the execution status of a test. The test suite can include any of these three states - Active, In Progress, and Completed. Multiple test suites and test plans can have the same test case. Firstly, a test plan is created. Following the creation of a test plan, test suites are created which comprises various tests. Based on the scope, or the cycle, test suites creation can be typically classified into three types – functional, non-functional, and maintenance. Functional testing verifies every feature of the software. On the contrary, non-functional testing deals with aspects like reliability, performance, usability. Maintenance testing is about having the same quality throughout the life cycle of the program, even if some operational changes occur.
