of units or components that are compiled together. After unit testing and component testing is successful, it can be implied that each unit and component is error-free. Then integration is done putting together these previously tested units as one unit to check for errors. Integration testing causes the flow of data and instructions between various components compiled together for testing.

5. **Regression Testing:** After a design passes the smoke test, various additional features are added in the design by the developers. These additional features might tamper with the other functionalities that were previously error-free. Regression testing is done to check whether any bugs are accidentally added into the design while adding other features and also to check whether the bugs that were removed previously from the design have not been incorporated into the design again.
6. **Sanity Testing:** Sanity testing consists of tests that are a subset of the tests done in regression testing. When a build or design is presented
