

after minor modifications or changes then instead of doing thorough regression testing, sanity testing is performed. Sanity testing checks whether the minor modifications have solved the previous problems of the build and whether these modifications have introduced any new error or problem. Tests present under sanity testing are related to the minor modifications of the previous build.

7. **System Testing:** System testing is done after compiling all the components into a system. System testing is done after the successful completion of unit testing, component testing, and integration testing. System testing is done to verify whether the system meets the functional, technical, and business requirements that are expected to be met by the system.
8. **User Acceptance Testing:** User acceptance testing (UAT) is done at the end when all other functionality testing is completed with successful results. In this last phase of functional testing, the performance of the system is tested in the jobs of the real world. This is done before handing over the system to the user, as a final testing method to ensure the satisfaction of the user.

- **Non-Functional Testing:** Functional testing checks all the functions that need to be performed by a system. Non-functional testing is done to check non-functional parameters like the efficiency of the system, the security of the system, etc. Non-functional testing checks the overall performance of the system. Common non-functional testings are:
 1. **Performance Testing:** Performance testing is carried out to find out the response time of the system, i.e. how quickly the system produces an output after receiving the input. A huge load and the database are loaded onto the system to check its response time.
 2. **Load Testing:** A system can be used by many users simultaneously, so load testing is necessary to check whether the system will be able to work under such conditions.

Standard test suite template format:

Test suites play a very vital role in the Software Development Life Cycle (SDLC). So it will be beneficial if all software developers obey a standard template format as a guideline in the creation of test suites. Test suites can be pre-built or custom created as per requirement. Let us now check out a standard format of a test suite template:
