

removal of a developer from his job. On the contrary, a good bug report helps to save time as there is no miscommunication in the team.

- **Not treating Quality Assurance as the final development stage:** Quality assurance should not be considered as the last phase of development. Constant testing should take place at each iteration before the components of development are implemented.
- **Testing includes team effort:** You should make sure that all the people included in the testing team has a good understanding of the project. This saves time and helps the team effectively cover the test cases. Keeping all the members in the loop helps save time.
- **Using efficient tools to make testing easy:** The tests written by testers should be easy to write and more importantly, easy to run. Making test cases easy to run will help developers check their code as soon as they write in IDE.
- **Testing of user documentation:** Any software developed usually has documentation provided so that users don't face any issue. This documentation should be verified and tested before publishing it for public use. The documentation of any software should be crisp and easily understandable.
- **Reduce risk to the extent possible using testing:** The main goal of testing software isn't to only find bugs. Testing should be done to minimize risk by actively finding and removing problems that can impact customers using that software. For instance, if a user finds a bug while transferring a certain amount frequently, it would lead to frustration on his end. The user might not even use the software again and leave a negative review.
- **Conducting code reviews frequently:** Having other developers review your code on a time-to-time basis will lead to finding bugs quickly. Pairing programming or writing code together can help to write bug-free code and improve its quality.
- **Keep the end-user engaged:** Having frequent feedback from customers who will be using the software helps to build a good product. A software developer should keep in mind the points to improve, as stated by the customers, and incorporate them into the product before making the final release of the product.
- **Adapt to new technologies:** Various tools are being developed for making the life of testers easy. These tools reduce the time for testing by helping to prepare edge test cases which are difficult to find at times. Thus, a tester should always keep learning and adapt to new tools/frameworks developed for testing.
