

journey involves the user coming to the landing page of the software or application, a series of transitions based on various user inputs, and a set of triggers.

- **Use of exploratory testing:** Exploratory testing is skipped at times by testers. However, exploratory testing can turn out to be important as it is done when the project is undergoing study. A deeper analysis of the functionalities will allow testers to comprehend how to proceed with testing.
- **Not skipping load testing:** Consider you have a product without any bugs and having a smooth interface. However, this product is not able to handle a large number of users at the same time. This can hamper scalability as the developed application can't handle enough traffic creating a bad impression on users. Hence, load testing is important to ensure the above condition does not arise.
- **Cheating on performance tests should be avoided:** A tester should never test on the low-end parameters by considering that peak conditions will not arise. For instance, the application you need to test has to allow 1000 users concurrently for an hour. You drop down the maximum number of allowed users to 500 and the time to 20 minutes. This will help you to show better performance initially. However, when the product is finally released and used by more than 1000 users for a longer duration, the performance will degrade.
- **Having agile beta tests:** Companies following the agile beta-testing policy release early to gather feedback from users and often release to improve the performance of the product.
- **Maximum test coverage to be done:** Divide your Application Under Test(AUT) into small functional segments. Having smaller functional segments help you to cover maximum test cases.
- **Experiment with unique behaviour to find bugs:** After completion of all the planned test cases, try designing some adverse situations that are rare.
- **Automate test cases when possible:** If there can be a certain rule for a test case, you should try to automate it by writing a script or building a tool. Automation helps you save time by not doing the same task multiple times.
- **Have a look at your competitors and see the mistakes made:** Checking out the lapses in earlier released products by competitors of the same category helps testers to design test cases for these unique scenarios.
