

- **Focus on quality over quantity:** Many testers feel that writing more test cases is the only way to test a product. However, this might not be the case always. A tester should focus on writing quality test cases rather than making repetitive checks with similar conditions.
- Have the right set of users for user testing: **Taking the feedback** of users before finally launching a product is a good practice. However, you should have the right set of users for using your product. For instance, if you chose a developer as a tester, he will generally advise you ways to improve your code. A person from a non-technical background can suggest ways to improve the User Interface.
- **Testers should try to provide causes of the failures for test cases:** Troubleshooting the main reason for application failure can help you find the solution to your problem. It is not mandatory, but a tester should try to find solutions besides logging the bugs.
- **Figuring out bottlenecks:** For instance, if you witness an application running slow, you can try finding the bottleneck. Identifying the bottleneck can be done by checking the speed of the application after removing certain features which might cause the application to slow down.
- **Identify patterns in code:** For instance, if you have to find errors in a piece of code, you try to find a pattern in the two codes. This will help to reduce the time taken to find bugs for the others.

Wrapping Up

Here in this chapter, we covered how you can build a software test suite for a project. The various types of software testing are also elucidated, providing testers with a clear insight on testing various modules of the software before finally launching the product.
