

Why do we need to do load testing?

If you are a true cricket fan, you surely must have heard the incident when a popular sports website crashed when millions of people started to access it simultaneously. The incident occurred in 2010 when Sachin Tendulkar scored a double hundred in a one-day international match. When he was batting on 199 runs, millions of cricket fans started to access the sports site to check whether he will score 200 or not.

This incident showed website developers that a website could crash due to high traffic. Currently, we have seen popular e-commerce sites face downtimes. The owners only focus on bringing great advertisement and investment. They do not show concern about optimal system performance to avoid such chaos.

These are the reasons why one must perform load testing-

- Load testing is probably the best way to ensure high performance, potential performance, and reliability.
- It is an excellent way to figure out errors or bugs in the site due to the absolute traffic load before they occur in real-time.
- Load testing will mitigate all possibilities of poor performance. It helps developers make plans that complement website performance management and monitoring capacities.

Goals of load testing

- To ensure a faster and smoother response time for every server request.
- To maintain high performance of a website system even with heavy online traffic
