

3. Percentiles

Percentiles are taken as the grouping of results based on their percentage as a whole.

What are the basics of load testing?

Load testing involves sending a large number of online HTTP traffic to a website or any web application server to figure out the performance, response rate, etc. It helps answer the following questions-

- Are there sufficient sources for servers such as CPU, memory, and network to handle the specific load?
- How quickly and smoothly is the server responding to the user request?
- How quickly and efficiently is the platform opening and performing?
- Is there a need to scale up the software or hardware for the modification?

The load testing of a website is performed on a genuine load testing software and requires multiple systems. The process starts with using a load testing software in a PC or laptop to generate a massive number of requests on a web server in a second computer machine. Though, for conducting a large-scale website load testing process, developers will need a cluster of computer machines to perform it precisely.

Uses of load testing software

The standard use of load testing software is to determine how many requests per second a website server can handle with high performance.

The test loading software is quite useful to identify the maximum capacity of a server. Here are a few uses of a load testing software:

1. Website- loading testing plan

To make a website loading testing plan, you must follow or consider some general steps to find out how well your website server performs and responds to heavy traffic. For this, you need to make sure you have all of the monitoring system resources. Next, check the server's highest response to a maximum per-second request. Lastly, check the total capacity of throughput when the server latency starts to show unfavorable results.

2. Monitoring lead testing resources

The load testing software is quite useful for acquiring latency and request information from the system. The testing software is also quite precise for monitoring other system metrics to observe the confinement of servers while
