

dealing with heavy traffic. The load testing monitoring resources are all about setting a system like Graphite and collectD. In monitoring, developers are solely concerned with the free memory and load of the CPU system. It will help them make better web strategies during website development.

3. Identify the highest latency

As discussed previously, the website load testing software is quite beneficial in determining the highest latency. To do this, you need to set the total duration of the test and the desired concurrency.

Concurrency is a parameter that shows how many connections are present in parallel with the server. Setting 100 is quite as safe as a default option. However, it is wiser to set your server set to find out how many parallel connections it can bear or handle.

After, find out a URL for the load test. It would help if the load testing software is sending requests at a fast rate. Then, watch how gradually the memory and CPU resources are consuming and CPU idle, reaching zero. It will show some errors. This will happen because the server will reach its highest limit.

After all the processes are completed, the software will present some statistics including requests per second data.

4. Highest practical throughput

It is recommended to have a genuine load testing software capable of transferring the load back a bit to measure the server's real performance on various levels of throughput during this stage or step. Some load testing software allows technicians to specify a specified interval between each server request.

Some proven tips to mitigate load

With the massive internet and digital technology trend, the number of online users is now increasing day by day. This means countless people are accessing sites and creating challenges for the supporting server staff.

A component of a website called origin server is the sole infrastructure on which an entire website depends. When the origin server reaches its capacity, the site will not support any more access.

So, what should you do to avoid shut-downs and downtimes? Here are some proven tactics that can help you to mitigate some load from your website:

- Use a content delivery system (CDN) for storing static content.
- Compress high-quality and large-sized images with editing tools like photoshop or any other photo editing tool.
