

framework should provide an authentic framework for automating APIs.

- Appium adheres to the philosophy of providing an open-source mobile automation framework.

These doctrines determine the success of the Appium architecture, hence making it a hot testing arena for developers.

Types of mobile applications

When it comes to mobile applications, several types direct the kind of testing that has to be conducted. These kinds of applications belong to Android, iOS, and Windows platforms. Appium automated the testing process for these kinds of applications on its framework. Let's take a look at these:

- **Native Mobile Applications:** The kind of applications that are written using the native software development kit of iOS, Android, and Windows.
- **Mobile Web Applications:** The kind of applications that can be accessed using the browsers of mobile phones such as Google Chrome or Safari. These browsers can either be the in-built default version of the phone or can be a third-party application.
- **Hybrid Mobile Applications:** These are apps that work on both the iOS and Android default browsers. They are developed using HTML and CSS for both the platforms. To optimise it for the various platforms, the applications are wrapped for the necessary platforms accordingly.

Appium gives you a lot of flexible options to test apps for the above three types. For example, you don't have to create two different sets of codes for two different platforms. Application code written for Android can be used for testing the app on iOS as well. The optimisation of the platform is what makes it one of the best app testing frameworks around the world.

Decoding the concepts of Appium

Before moving on to the nitty-gritty of the Appium App testing framework, let's look into the various concepts of Appium. The terminologies shall help you to go about the test framework in a much better manner. Below is the list of Appium concepts for developers:

Client/Server Architecture

Appium works on the REST API Architecture. It is a simple architecture that promotes the functions of a Client/Server Architecture. Clients are given the option of executing their commands to which the framework provides an HTTP response.
