

This architecture allows for flexibility in the field of app testing frameworks wherein it offers a lot of possibilities. It enhances the work done by developers by providing a basic demand-supply framework for app testing.

Sessions

While working on an Automation process, clients always have to work in “sessions”. A Session denotes a testing time frame generated for the task onboard. They have to initiate an automated session by sending their requirements to the server. Usually, clients send a session request by using a JSON framework which is also called as “desired capabilities”. The server responds with a Session ID, which acts as the touchpoint for the developers during the entire testing process.

Desired Capabilities

It is the set of keys and values that is sent over to an Appium Server for the kind of automation services the client is interested in. These values denote the basic needs of the client, which makes the testing process viable for the developers.

Appium Server

Appium server is built on Node.js. The server can be easily installed directly from the source for easy use of this amazing automating framework.

Appium Clients

Appium clients are those client libraries that support the automating framework’s extension to the WebDriver protocol. The specific client libraries are as follows:

- PHP
- JavaScript
- Python
- Java
- Ruby
- C++

You can use these clients instead of the regularly used WebDriver protocol.

Appium Desktop

Appium Desktop is a Graphic User Interface (GUI) wrapper used for the Appium Server which can be downloaded for various platforms. This GUI
